The Alaska Fisheries Data Series was established in 1994 to provide public access to unpublished study results. These reports are intended to document short-term field studies limited in or lacking statistical interpretation. Reports in this series receive limited internal review prior to release and may be finalized in more formal literature in the future. Consequently, these reports should not be cited without approval of the author or the Division of Fisheries Resources.

Disclaimer: The mention of trade names or commercial products in this report does not constitute endorsement or recommendation for use by the federal government.

*Abstract.* – From June 28 to September 19, 2002 a resistance board weir was used to collect abundance, run timing, and biological data from salmon returning to spawn in the Kwethluk River, a tributary to the lower Kuskokwim River. This was the third year of a cooperative project between the U.S. Fish and Wildlife Service and the Organized Village of Kwethluk. This project was initiated under the Federal Subsistence Fishery Management program to obtain the reliable data necessary for managing the Yukon Delta National Wildlife Refuge fishery resources that support intense commercial and subsistence uses.

A total of 34,681 chum *Onchorhynchus keta*, 8,395 chinook *O. tshawytscha*, 272 sockeye *O. nerka*, 1,415 pink *O. gorbuscha* and 23,298 coho *O. kisutch* salmon were counted through the weir. Peak weekly passage occurred as follows: June 30 to July 6 for sockeye, July 7 to 13 for chinook and pink, July 14 to 20 for chum, and September 1 to 7 for coho salmon.

Age and sex data was collected for all species but pink salmon. Dominant age groups were as follows: 0.3 for chum, 1.4 for female chinook, 1.2 for male chinook, 1.3 for sockeye, and 2.1 for coho salmon. Overall percentage of females was as follows: 47% for chum, 21% for chinook, 60% for sockeye, and 45% for coho salmon.

## Introduction

The Kwethluk River, a lower Kuskokwim River tributary located on the Yukon Delta National Wildlife Refuge (Refuge), provides important spawning and rearing habitat for chum *Onchorhynchus keta*, chinook *O. tshawytscha*, sockeye *O. nerka*, pink *O. gorbuscha*, and coho *O. kisutch* salmon (Figure 1) (Alt 1977; U.S. Fish and Wildlife Service 1992). Adult salmon returning to the Kwethluk River migrate 159 river kilometers (rkms) through the lower Kuskokwim River before reaching the Kwethluk River, and then migrate upstream as many as 160 rkms to reach spawning grounds. In the lower Kuskokwim River, salmon pass through one of Alaska's most intensive subsistence fisheries (Burkey et al. 2001; U.S. Fish and Wildlife Service 1988).

The Alaska National Interest Lands Conservation Act (ANILCA) mandates that salmon populations and their habitats be conserved in their natural diversity within the Refuge; that international treaty obligations be fulfilled; and that subsistence opportunities for local residents be maintained. Salmon escapement studies for the lower Kuskokwim River tributaries on the Refuge are ranked as priorities in the Refuge Fishery Management Plan (U.S. Fish and Wildlife Service 1992). Compliance with ANILCA mandates, however, are not ensured when reliable data regarding fish stocks originating within the Refuge are not available.

Adequate escapements to individual tributaries and main stem spawning areas are required to maintain genetic diversity and sustainable harvests, but management is complicated by the mixed stock nature of the Kuskokwim River fishery. Managers attempt to distribute the catch over time to avoid overharvesting individual stocks, since each may have a distinct migratory timing (Mundy 1982). Stocks or species returning in low numbers or early and late portions of the runs may be overharvested incidentally during the intensive harvesting of abundant stocks. Escapement data are lacking on many of these individual stocks in the Kuskokwim River drainage and are needed for more precise management.

In accordance with ANILCA mandates, the U.S. Fish and Wildlife Service (Service) initiated a three-year study of the Kwethluk River in 1992 to: (1) enumerate adult salmon; (2) describe the run timing of chum, chinook, sockeye, pink, and coho salmon returns; (3) estimate the age, sex, and length composition of adult chum, chinook, sockeye, and coho salmon populations; and (4) identify and count other fish species passing through the weir. High water precluded the installation and operation of the weir in 1991, and the weir was operated only in 1992.

Village leaders passed resolutions opposing the weir in September 1992, consequently discontinuing weir operations. In 1996, the Association of Village Council Presidents (AVCP) initiated a counting tower project, which operated through 1999. Complete counts for chum, chinook, and sockeye salmon were obtained only in 1996 and 1997 because high water delayed operations until late July in 1998 and 1999. In all years of the tower project, high water prevented operations beyond mid-August; therefore, few data exist regarding the abundance and run timing of coho and pink salmon for those

years. Additionally, sampling for age, sex, and length information was unsuccessful in 1996 and 1997, and sampling was discontinued in successive years (Cappiello and Sundown 1998; Cappiello and Chris 1999). No comprehensive sampling data exist for the years of tower operation.

On October 1, 1999, the Secretaries of Interior and Agriculture expanded federal subsistence fisheries management in Alaska under Title VIII of ANILCA. To meet this management responsibility, the Federal Subsistence Board established the Fishery Resource Monitoring Program to gather information on fish stock status and trends, subsistence harvest patterns, and traditional ecological knowledge. This program funds studies to gather, analyze, and report information needed to manage subsistence fisheries. Salmon runs originating in the Kwethluk River support subsistence fisheries in both the Kwethluk and Kuskokwim Rivers. Because of the importance of the Kwethluk River, this weir project was one of the first projects funded under this program in 2000. The Kenai Fish and Wildlife Field Office (KFWFO) and the Organized Village of Kwethluk (OVK) have cooperatively conducted this project during 2000, 2001, and 2002.

### **Study Area**

The Kwethluk River is in the lower Kuskokwim River drainage (Figure 1). The region has a subarctic climate characterized by extremes in temperature. Temperatures range from summer highs near 15°C to average winter lows near -12°C (Alt 1977). Average yearly precipitation is approximately 50cm with the majority falling between June and October. The rivers generally become ice free in the slow-moving sections by early May and freeze-up occurs in late November. The Kwethluk River originates in the Eek and Crooked Mountains, flows northwest approximately 222 km, and drains an area of about 3,367 km<sup>2</sup>. Braiding and gravel substrates are found in the middle section of the river where the weir was placed. Below the middle section, the lower 47 km consists of a deeper, muddy-bottomed channel averaging 53 m in width (Alt 1977). Turbid water conditions that also are characteristic of this lower section are the result of active stream cutting on tundra banks.

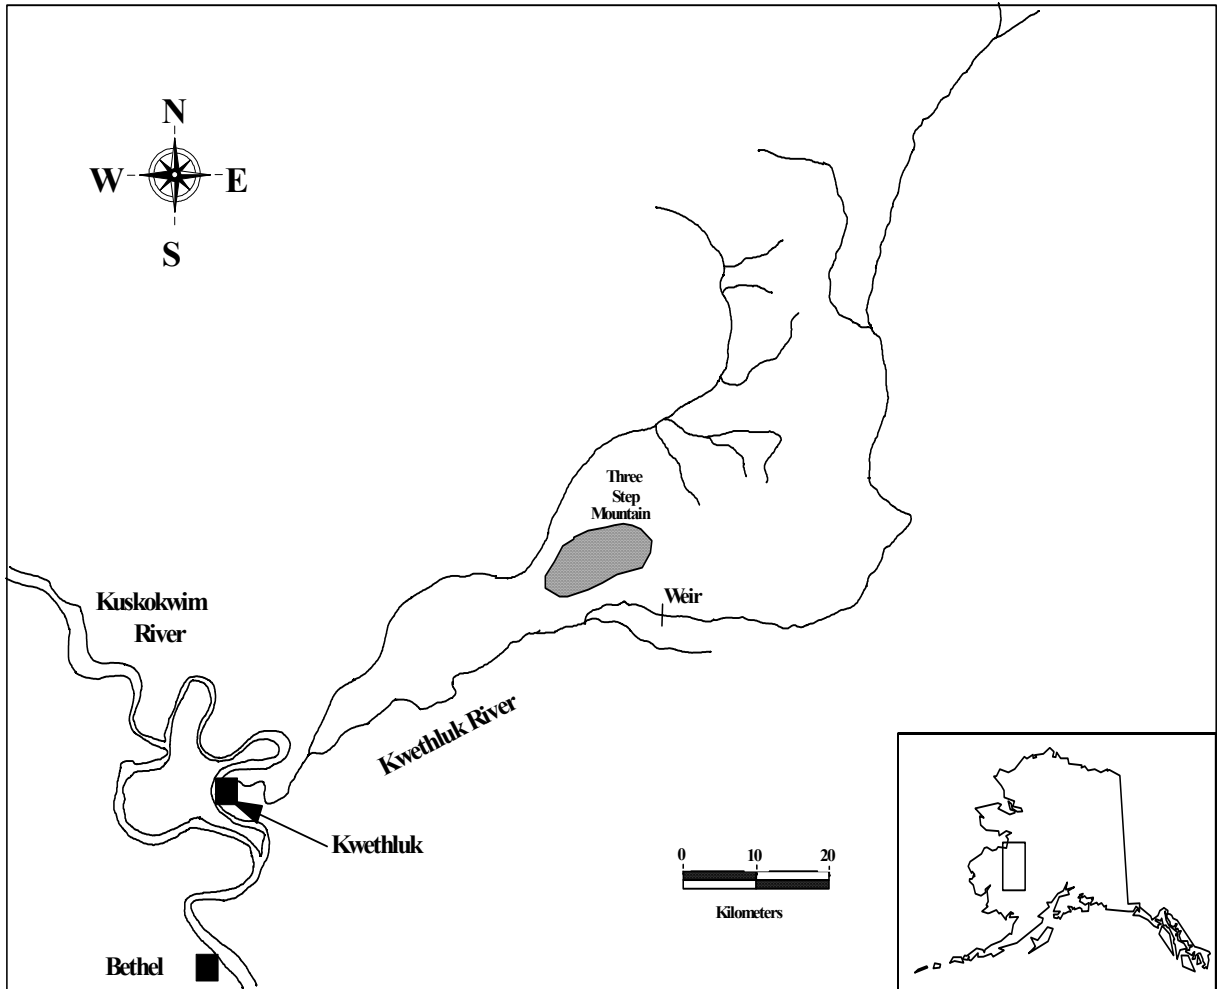

Figure 1. – Location of Kwethluk River weir.

## Methods

### *Weir Operation*

A resistance board weir (Tobin 1994) spanning 56 m was installed in the Kwethluk River ( $62^{\circ}07'N$ ,  $162^{\circ}48'W$ ) approximately 88 rkm upstream from the Kuskokwim River and 43 air-km east of Kwethluk, Alaska (Figure 1). This location is approximately 2.4 rkm downstream from the 1992 weir site described by Harper (1998). The weir was moved downstream to this section of river in 2000 due to a change in channel morphology at the old location. A staff gauge was installed upstream of the weir to measure daily water levels. Staff gauge measurements were correlated to correspond with the average water depth across the river channel at the upstream edge of the weir. Water temperatures were collected daily at the site, June 28 through September 19, generally between 0800 and 1200 hours.

One live trap and one counting passage way were installed to facilitate sampling and efficient fish passage during various river stage heights. All fish were enumerated to species as they passed through the live trap or counting passage way (Harper 1998). Salmon and resident species that did not pass through these areas, but escaped upstream through the gaps between pickets were not counted. Picket spacing is 4.8 cm, wider than the 3.5 cm spacing used in 1992. Panels with wider picket spacing were designed to remain functional during greater water flow and allow passage of smaller pink salmon between pickets. Fish were passed and counted intermittently between 0001 hours and midnight each day. The duration of counting sessions varied depending on the intensity of fish passage through the weir and was recorded to the nearest 0.25 hour at each counting station.

The weir was inspected for holes and cleaned daily. An observer outfitted with snorkling gear checked weir integrity and substrate conditions. Cleaning consisted of raking debris from the upstream surface of the weir or walking across each panel until it was partially submerged, allowing the current to wash accumulated detritus downstream.

#### *Estimates of missed salmon passage*

For days when high water or a late start prevented accurate counts, estimates were made using percent passage data from previous years with complete data. The passage for the  $j$ th day with missing data was estimated as:

$$\hat{n}_j = \left[ \frac{\sum_{i=1}^D \theta_i n_i}{1 - \sum_{i=1}^D \theta_i p_i} \right] p_j, \quad (1)$$

where

$n_i$  = weir passage on day  $i$ ,

$p_i$  = proportional passage on day  $i$  based on historical data,

$\theta_i$  = an indicator variable defined as 1 if passage was observed on day  $i$ , 0 otherwise, and

$D$  = number of days in the season.

#### *Biological Data*

Sample weeks, or strata, began on Sunday and ended the following Saturday. However, a partial week of weir operation shortened the length of the last strata. Sampling generally commenced near the beginning of the week, and an effort was made to obtain a weekly

quota of 210 chum, 210 chinook, 210 sockeye, and 170 coho salmon in as short a period (1-3 days) as possible, to approximate a pulse or snapshot sample (Geiger et al. 1990). All target species within the trap were sampled to prevent bias.

Fish sampling consisted of measuring length, determining sex, collecting scales, and then releasing the fish upstream of the weir. Length was measured from mideye to the fork of the caudal fin and rounded to the nearest 5mm. Sex was determined by observing external characteristics, including presence of ovipositor or gametes. Scales were removed from the preferred area for age determination (Koo 1962, Mosher 1968). Three scales were collected from each chum salmon, one from each sockeye salmon, and four scales from each chinook and coho salmon. Scale impressions were made on cellulose acetate cards using a heated scale press and examined with a microfiche reader. An Alaska Department of Fish and Game (Department) biologist determined age and reported results according to the European Method (Koo 1962).

Mean lengths of males and females by age were compared using a Welch's two-tailed  $t$  test for samples of unequal variance at  $\alpha=0.05$  (USFWS 2003). Age and sex composition were estimated using a stratified sampling design (Cochran 1977). Chi-square contingency table analysis was used to test for differences in age composition between the sexes. Because the standard test only applies to data collected under simple random sampling, adjustments were made to the test statistic, following Rao and Thomas (1989), to account for the impact of our stratified sampling design on the results. The  $O^2$  statistic, hereafter referred to as  $O^2(\delta)$ , was divided by the mean generalized design effect, as a first-order correction to the standard test (Rao and Thomas 1989). Estimated design effects for the cells and marginals are presented in the results. Age and sex specific escapements in a stratum,  $\hat{A}_{hij}$ , and their variances,  $V[\hat{A}_{hij}]$ , were estimated as:

$$\hat{A}_{hij} = N_h \hat{p}_{hij} ; \quad (2)$$

and

$$\hat{V}[\hat{A}_{hij}] = N_h^2 \left( 1 - \frac{n_h}{N_h} \right) \left( \frac{\hat{p}_{hij}(1 - \hat{p}_{hij})}{n_h - 1} \right) \quad (3)$$

where

$N_h$  = total escapement of a given species during stratum  $h$ ;

$\hat{p}_{hij}$  = estimated proportion of age  $i$  and sex  $j$  fish of a given sample in stratum  $h$ ; and

$n_h$  = total number of fish, of a given species, in the sample for stratum  $h$ .

Abundance estimates and their variances for each stratum were summed to obtain age and sex-specific escapements for the season, as follows:

$$\hat{A}_{ij} = \sum \hat{A}_{hij} ; \quad (4)$$

and

$$\hat{V}[\hat{A}_{ij}] = \sum \hat{V}(\hat{A}_{hij}) ; \quad (5)$$

where

$\hat{A}_{ij}$  = estimated total escapement for age  $i$  and sex  $j$  fish of a given species.

## Results

### *Weir Operation*

Several attempts at early installation of the weir were made but were unsuccessful due to high water. The weir was installed and operational on June 28, 2002. Due to a late start, a small proportion of both the chinook and chum salmon escapement may have been missed. Estimates of the missed portions were made. During the operational period, no major difficulties were experienced. The last day of counts was September 19, 2002. Water level data was collected on a daily basis (Appendix 1).

### *Biological Data*

A total of 35,681 chum, 8,395 chinook, 272 sockeye, 1,415 pink, and 23,298 coho salmon were counted through the weir. Estimates of missed passage give a total count of 35,854 chum and 8,502 chinook salmon. Additionally, 49 Dolly Varden *Salvelinus malma*, 524 whitefish *Coregonus* spp., and 8 rainbow trout *Onchorhynchus mykiss* were also counted.

*Chum salmon*—A total of 35,681 chum salmon passed through the weir from June 28 to September 13, 2002. Estimates of the uncounted early run bring the total to 35,854. Peak passage (N = 9923) occurred during the week of July 14 to 20 (Figure 2). Median passage occurred on July 17. Gillnet marks were observed on approximately 3% (N = 979) of the chum salmon passing through the weir (Appendix 2).

Four age groups were identified from scale samples (0.2, 0.3, 0.4, 0.5). Analysis indicated a significant difference in age composition between the sexes ( $X^2(\hat{\delta})=200.8$ ,  $df=3$ ,  $P<0.001$ ). For both male and females, the 0.3 age group predominated (68% and 74% respectively), and the 0.3 and 0.4 age groups combined for over 90% of the total. Females comprised an estimated 47% of the total escapement, and over 50% in the last two strata (Figure 3, Appendix 3).

Results of t-test analysis indicate that males were larger than females at all ages with sufficient sample sizes (0.2, 0.3, 0.4, 0.5) to allow for analysis (Appendix 4).

*Chinook Salmon*—A total of 8,395 chinook salmon passed through the weir from June 28 to September 8, 2002. Estimates of the uncounted early run bring the total to 8,502. Peak passage ( $N = 2,549$ ) occurred during the week of July 7 to 13 (Figure 2). Median passage occurred on July 9. Gillnet marks were observed on approximately 4% ( $N = 353$ ) of chinook passing through the weir (Appendix 2).

Four age groups were identified from samples (1.2, 1.3, 1.4, 1.5). Analysis indicated a significant difference in age composition between the sexes ( $X^2(\hat{\delta}) = 305.2$ ,  $P < 0.001$ ,  $df = 3$ ). Throughout the season, age 1.4 was the predominant age group for females (61%). For males, the 1.2 age group was predominant (59%). In males, ages 1.2 and 1.3 accounted for the majority (92%) of the escapement. In females, ages 1.3 and 1.4 accounted for the majority (92%) of the escapement. Females comprised an estimated 21% of the total escapement. Males dominated throughout the season, never falling below 70% of escapement (Figure 3, Appendix 5)

Figure 2. – Weekly escapement, including estimates of missed passage, of chum, chinook, sockeye, pink and coho salmon, Kwethluk River weir, Alaska, 2002.

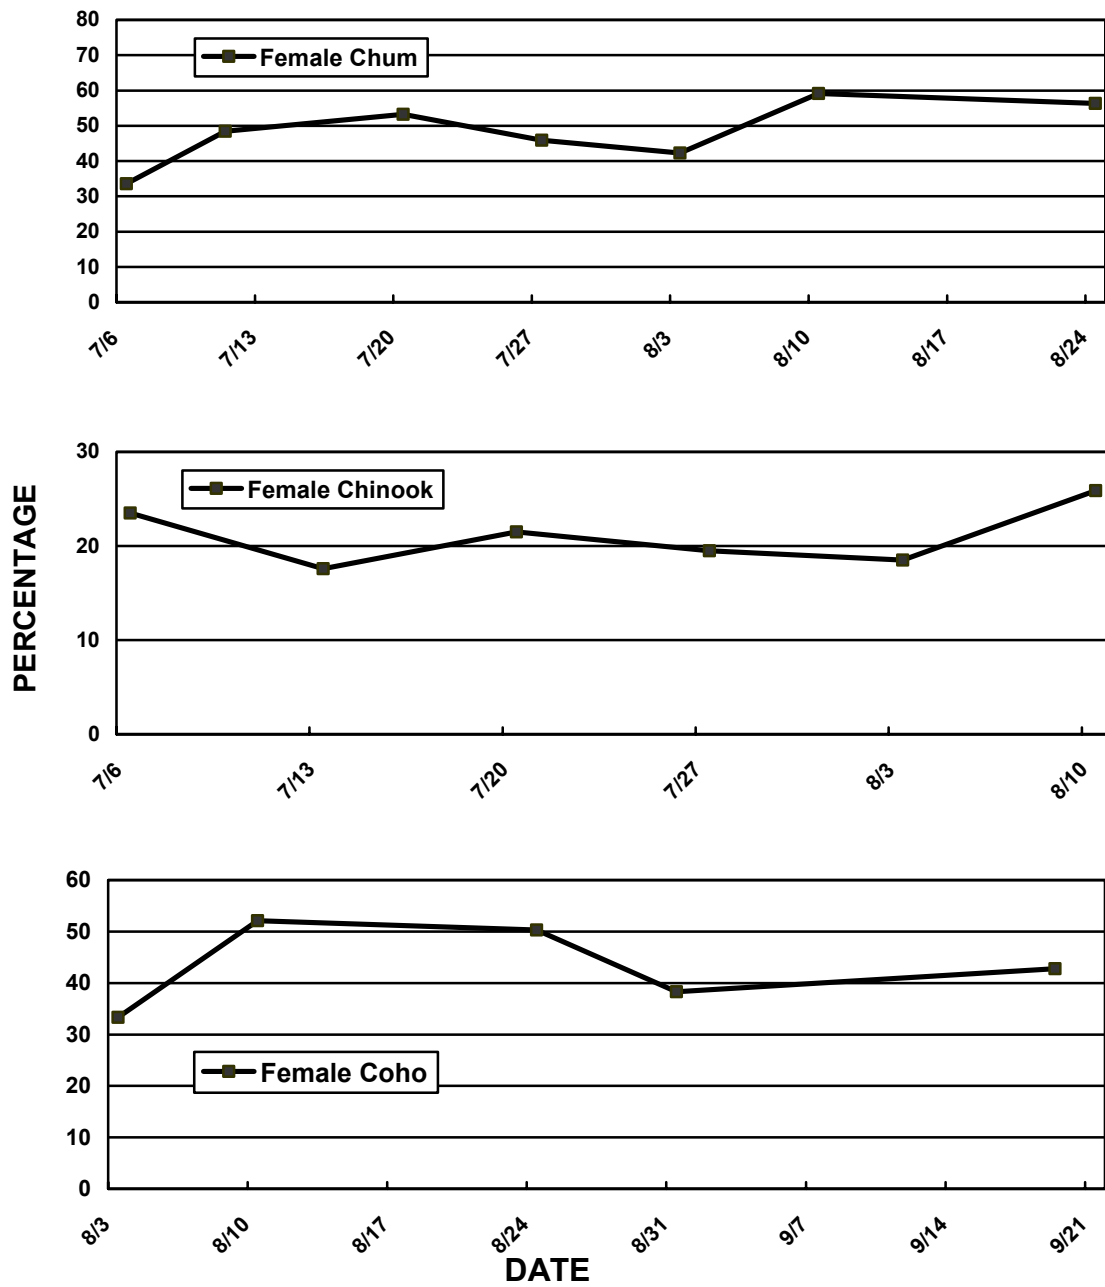

Figure 3. – Percent composition of females for chum, chinook, and coho salmon, by sampling stratum (ending date), Kwethluk River weir, Alaska, 2002.

Females were larger than males for ages 1.3 and 1.4 (Appendix 4). Sufficient samples for other ages were not available.

*Sockeye Salmon*—A total of 272 sockeye salmon passed through the weir from June 29 to August 24. Peak passage ( $N = 95$ ) occurred during the week of June 30 to July 6 (Figure 6). Median passage occurred on July 11. No sockeye salmon with gillnet marks were observed (Appendix 2).

Four age groups were identified from scale samples (1.2, 1.3, 1.4, 2.3). Analysis indicated no significant difference in age composition between sexes ( $X^2(\hat{\delta}) = 0.624$ ,  $df=3$ ,  $P=0.891$ ). However this may be due to small sample sizes. Overall, males comprised an estimated 40% of the total escapement. The 1.3 age group was predominant in both males and females (71% and 69%, respectively). Due to the small overall size of the escapement, several strata had small or nonexistent sample sizes (Appendix 6).

*Pink Salmon*—Weir picket spacing allows some pink salmon to pass upriver uncounted, however, a total of 1,415 were counted through the weir. Peak passage ( $N = 287$ ) occurred during the week of July 7 to 13 (Figure 7). Median passage occurred on July 25. Three pink salmon were observed to have gillnet marks. Pink salmon were not sampled for age, sex, or length (Appendix 2).

*Coho Salmon*—A total of 23,298 coho salmon passed through the weir from July 29 to September 19. Peak passage ( $N = 7608$ ) occurred during the week of September 1 to 7 (Figure 8). Median passage occurred on August 28. Gillnet marks were observed on 1% ( $N = 254$ ) of coho salmon passing through the weir (appendix 2).

Three age groups were identified from scale samples (1.1, 2.1, 3.1). Analysis indicated a significant difference in the age composition between sexes ( $X^2(\hat{\delta}) = 64.5$ ,  $df=2$ ,  $P<0.0001$ ). Females comprised an estimated 45% of the total escapement. Throughout the season, males comprised the majority of the escapement, with the exception of two periods where females held a slight majority (Figure 9, Appendix 7). For both males and females the 2.1 age group was predominant (93% and 93%, respectively).

Males were larger than females at age 2.1 ( $P=0.001$ ). At age 3.1 differences in lengths were not considered significant ( $P=0.780$ ). Age 1.1 did not have sufficient sample size to allow for analysis (Appendix 4).

## Discussion

### *Weir Operation*

High water prevented the installation of the weir until June 28. Data from both 1992 and 2000 indicate that chum and chinook salmon are generally present and passing the weir

prior to that time. Estimates of the missed proportion were constructed and added to the data for analysis. Counts for other species are considered complete.

Picket spacing on the weir is such that many pink salmon and resident fish species are able to pass between pickets. Other salmon species are effectively blocked. Thus, counts of pink salmon, whitefish, northern pike, rainbow trout, and Dolly Varden are below actual passage.

The Kwethluk River weir has had full seasons of operation in 1992, 2000, and 2002. From 1993 to 1999 the weir was not operated due to opposition from the Organized Village of Kwethluk. From 1996 through 1999 AVCP operated a counting tower near the present location of the weir, but had mixed results due to high and turbid water, and did not gather age, sex, and length samples. In 2001, high water prevented installation of the weir until August. It was operational from August 12 to September 13.

### *Biological Data*

The Kuskokwim River chum and chinook salmon rebuilding plan remained in effect during 2002. No commercial fishing season for chum or chinook salmon occurred during 2002 and subsistence fishing was limited to four days per week. These two factors helped increase escapement to the spawning grounds in 2002 (Alaska Department of Fish and Game, 2002)

*Chum Salmon*—Estimated chum salmon escapement during the 2002 season ( $N = 35,854$ ) was above 1992 weir (30,595) and 1996 tower (26,049) counts, but well above the last complete weir count of 11,691 during the 2000 season (Appendix 8). Median escapement (July 17) was only one day later than in 2000. Gillnet marks were observed on 3% of the sampled chum salmon. This the same as in 2000 (Harper and Watry 2001) and well below the 5% observed in 1992 (Harper 1998). The 47% proportion of females is slightly less than the 50% observed in 2000. By period, the proportion of females showed the same pattern of increase-decrease-increase seen in 2000 (Harper and Watry 2001).

*Chinook Salmon*—Estimated chinook salmon escapement ( $N = 8,502$ ) is more than twice the 2000 escapement ( $N = 3,547$ ), the last year for which a full count is available, but less than the 1992 weir count ( $N = 9,675$ ) (Harper and Watry 2001). The median passage date of July 9 was earlier than in 2001 (July 13). The proportion of gillnet marked fish observed, 4%, was slightly higher than in 2000 (4%), but well below the 10% observed in 1992 (Harper and Watry 2001, Appendix 8). As in 2000, males made up the majority of the overall run and were the majority in each sampling strata. Females made up 21% of the total escapement, less than in both the 1992 (25%) and 2001 (22%) seasons (Harper and Watry 2001).

*Sockeye Salmon*—The Kwethluk River is not known for having a large population of sockeye salmon, and they are harvested as by-catch with other species. Escapement in 2002 ( $N = 272$ ) was well below the 1,049 counted in 2000 (Appendix 8). No sockeye

salmon with gillnet marks were observed. This is the first year this has happened, but it may be an artifact of the small number of fish passing the weir. The proportion of females (60%) was higher than in 2001 (49%) and nearly identical to the 60% observed in 1992.

*Pink Salmon*—The observed pink salmon escapement of 1,415, is very close to the 1,407 observed in 2000 (Harper and Watry 2001). These are the only two years that can be compared, due to the wider picket spacing used in the weir panels that allows some pink salmon to escape upstream without being counted. These counts should be considered indicators of relative abundance and run timing.

*Coho Salmon*—The observed count for coho salmon ( $N = 23,298$ ) is considered to be complete. This is the second lowest escapement observed at the weir, only slightly greater than the 21,535 estimated escapement in 2001 (Roettiger et al. 2002). Compared to the 2001 and 2000 ( $N = 25,610$ ) escapements, 2002 appears average (appendix 8). Median run timing, August 27, compares well with the timing of the 2001 run (August 25), but is a bit late compared to 2000 (August 21).

The proportion of gillnet marked coho salmon (1%) was the lowest ever recorded at the weir (1992 3%, 2000 2%, 2001 2%) (Harper and Watry 2001, Roettiger et al. 2002). This may be due to the fact that only two commercial openings occurred during the coho migration. Both were characterized by low participation and low total catch.

Females comprised 45% of the total coho salmon escapement. This compares well with the 43% observed in 1992 and the 45% observed in 2000. In 2001, the proportion of females was 51%, but may have been skewed due to small sample size (Roettiger et al. 2002).

### **Recommendations**

The Kwethluk River weir continues to be an important tool for monitoring salmon stocks originating on the Yukon Delta National Wildlife Refuge and providing information to the Alaska Department of Fish and Game and Federal In season Manager for management of Lower Kuskokwim River fisheries. It is recommended that the weir project continue to be operated on a yearly basis. It is further recommended that operations be continued into September to get as complete a count of coho salmon as possible. Early installation, prior to spring runoff, is also recommended.

## **Acknowledgements**

This project (FIS 00-019) was funded under Cooperative Agreement 7018J258 between the U.S. Fish and Wildlife Service and the Organized Village of Kwethluk. The Cooperative Agreement provided funding to the village, to help with their capacity in becoming active partners in monitoring important Yukon Delta National Wildlife Refuge fishery resources that are used for subsistence by the people of Kwethluk and other Kuskokwim River villages. As a partner, Kwethluk hired personnel locally and purchased operational supplies and equipment. The Organized Village of Kwethluk also provided the administrative support and direction to their employees and promoted project understanding to the people of the village. Many village residents contributed to the success of the Kwethluk weir. Abraham Alexie Jr., Oscar Larson, Robert Michael, and Frank Frank were instrumental in counting fish, staging, and resupply at the weir. John Owens, Chariton Epchook, and Boris Epchook helped with administration and other support functions. Oscar Larson also provided direct project support, administration of village reports, and inventory controls.

Special appreciation is extended to those other people who contributed to this project: Ken Gates and Charlie Weeks (USFWS) helped with the installation and early training of the crews. Dan Nolfi, Ty Wyatt, and Joe Cadieux (USFWS) staffed the weir. Thanks to the entire Yukon Delta National Wildlife Refuge staff for their support. We also appreciate the assistance of the Alaska Department of Fish and Game, Commercial Fisheries Management and Development Division, A-Y-K Region, and Larry DuBois and Doug Molyneaux for scale sample analysis.

8/19, 8/20 (8/11 - 8/24)	Male	Mean Length	565	583	597
		Std. Error		5	9
		Range	565 - 565	490 - 680	585 - 615
		Sample Size	1	71	3
	Female	Mean Length		579	630
		Std. Error		4	26
		Range		465 - 660	575 - 720
		Sample Size	0	71	5
8/27 (8/25 - 8/31)	Male	Mean Length	530	603	595
		Std. Error		4	19
		Range	530 - 530	490 - 675	475 - 670
		Sample Size	1	84	10
	Female	Mean Length	590	583	560
		Std. Error		6	14
		Range	590 - 590	450 - 655	530 - 610
		Sample Size	1	53	5

Appendix 11. – (Page 2 of 2)

Sampling Dates (Stratum Dates)			Brood Year and Age Class		
			1999	1997	1997
			1.1	2.1	3.1
9/2, 9/3 (9/1 - 9/19)	Male	Mean Length	535	611	595
		Std. Error	40	4	90
		Range	495 - 575	505 - 675	505 - 685
		Sample Size	2	84	2
	Female	Mean Length	575	597	613
		Std. Error		3	26
		Range	575 - 575	510 - 650	565 - 655
		Sample Size	1	64	3
	Seasonal	Mean Length	532	598	589
		Std. Error	35	2	20
		Range	440 - 625	450 - 680	435 - 685
		Sample Size	7	284	23
	Female	Mean Length	580	586	599
		Std. Error		2	11
		Range	575 - 590	450 - 680	450 - 720
		Sample Size	2	230	24

Appendix 12. – Daily counts for all species, including effort, net marked salmon, and estimates of missed passage, Kwethluk River weir, Alaska, 2002.
